Abstract

Background: Stillbirth is associated with a wide range of factors. The aim of study was to assay the prevalence of still birth at 28th week of gestation or later. In addition, it strove to identify the factors associated with stillbirth among women in Eastern Ethiopia in 2021.

Methods: The design of the study was cross-sectional, and it was conducted at a public hospital, Harar, in Ethiopia, from March 10 to May 10, 2021. A census sampling method was used to select 336 participants for the study. Information on socio-demographic status, maternal health, pregnancy, labor, and birth outcome was collected through a structured checklist. Bivariate and multivariate logistic regressions were used to identify factors associated with still birth.

Results: In this study, the prevalence of stillbirth was 12.6%. In bivariate analysis, mother age, place of residence, premature rupture of membranes, antepartum hemorrhage, gestational age, hypertensive disorder, congenital anomaly, partograph use during pregnancy, and the previous history of still birth among mothers were significantly associated with stillbirth. After adjusting confounder variables, significant factors associated with stillbirth were: high maternal age, rural residential areas, the use of partograph during labor and the previous history of still birth.

Conclusion: This finding of this study indicated that the high prevalence of stillbirth is a big health care concern in Hara, Eastern Ethiopia. Therefore, it is necessary to focus on it further in order to identify and mitigate issues related to advanced maternal age, rural residents, the previous history of stillbirth, and partograph plotting in labor factors.

Keywords: Delivery, Prevalence, Risk factors, Stillbirth, Ethiopia

Introduction

The description of still birth is different in developed versus developing countries. In some middle-income and high income countries, thresholds vary from 18 to 22 weeks, while it reaches up to 28 weeks in low income countries (1). So, for international comparability purpose, World Health Organization (WHO) defines stillbirth as a fetus born dead at 28th week of gestation or more with a birth weight of ≥ 1000 g (2). Stillbirth can occur in either the antepartum period (before labor) or in the intra-partum period (during labor and before birth). Death after birth (and up to 28 days post-birth) is known as neonatal death (3). It is a strong indicator of the quality of antenatal and obstetric care (4). Every year, an estimated 2.6 million stillbirths occur worldwide, with

up to 98% occurring in middle-income and low countries. While the average stillbirth rate in high-income countries is 3 per 1000 births, the rates observed in Southern Asia and many settings in sub-Saharan Africa are up to 10-fold higher (5). Ethiopia is among the countries with the highest stillbirth rate worldwide (6). According to the 2016 and 2019 Ethiopian Demographic and Health Survey (EDHS. 2016 and EDHS. 2019) report, the stillbirth ratio was 11 and 12 per 1000 live births (7, 8).

Factors associated with stillbirth were multidimensional and complex. They include: maternal factors, fetal medical conditions, environmental exposures, and psychosocial stressors (9). Stillbirth reports come from officially registered deaths; thus, they could be under reported due to low institutional delivery, high home delivery, the custom of

Email: arifhussen.ah@gmail.com

community towards newborn death (they accept it as normal) , and the low utilization of vital registration in the country (10).

There is paucity in research regarding the prevalence and the determinants of stillbirth. Hence, this study aimed to assess the prevalence of stillbirth at 28th week of gestation or later. It also strove to identify the factors associated with stillbirth among women in Eastern Ethiopia in 2021. The findings of the study may help reduce some of the risk factors for stillbirth.

Materials & Methods

The design of the study was cross-sectional, and it was conducted at Hiwot Fana Specialized University Hospital in Harar, Ethiopia, from March 10 to May 10, 2021. The city is located east of Ethiopia, about 525 Km from Addis Ababa. Statistical calculation of sample size is based on estimated 8.6% in Negest Elene Mohammed Memorial General Hospital in Hosanna Town, SNNPR, Ethiopia. In order to determine the sample size with 95% significance level, the margin of error of 3%, and a 10% non-response rate were calculated through a single population proportion formula, and the estimated value was 370.

Ethical clearance was obtained from Harar Health Science College [Ref. no. HHSC-231/2021]. A census sampling method was used to select participants for the study. Consent was obtained from the administrative bodies of the hospital and from the participants. The data were collected through a pretest and a structured checklist, which was developed in English and was adapted from the literature related to stillbirth and was modified according to the local context. The questionnaire consists of information on socio-demographic status, maternal health, pregnancy, labor, and birth outcome. The questionnaire was administered by the interviewer. After data collection, the questionnaire was checked for completeness and then coded.

The data were entered into Epi-info version 3.5.3 and were then exported, cleaned and analyzed through SPSS version-21. Descriptive analyses were performed and bivariate analyses were used to find out the association between independent variables. Variables with a $p < 0.05$ in the bivariate analysis were entered into multiple logistic regression, and variables with $p < 0.05$ in the multivariate analysis were considered to have statistically significant associations.

Results

A total of 336 (98.9%) mothers participated in the study. Among them, 176 (52.4%) were between 18-24 years of age. Of the total, 167 (49.7%) were rural residents, and 284 (85.5%) of them were married (Table 1).

Table 1. Demographic characteristics of women attended deliveries in University Hospital, Eastern Ethiopia, 2021 (n=336)

Variable	Category	f	%
Age	18-24	176	52.4
	25-34	129	38.4
	>35	31	9.2
Marital status	Single	13	3.87
	Married	284	84.52
	Divorced	33	9.82
	Widowed	6	1.79
Place of residence	Urban	169	50.3
	Rural	167	49.7

Of the total, the prevalence of stillbirth was 12.5%. Almost one-third of the women (33.3%) had chronic diseases (such as diabetes mellitus and cardiac disease). The history of abortion and stillbirth were 11.6% and 12.5%, respectively. Only six women (1.8%) were HIV/AIDS (Table 2).

Only 6 (1.8%) of neonates were born with congenital anomaly, 70 (20.8%) were low birth weight, and 216 (64.3%) of neonate were male (Table 3). In bivariate analysis, mother age, place of residence, premature rupture of membranes (PROM), antepartum hemorrhage (APH), gestational age, hypertensive disorder, congenital anomaly, partograph use during pregnancy, and the previous history of still birth among mothers were significantly associated with stillbirth. Nevertheless, the adjusted odds ratio showed no significant association between stillbirth with factors such as PROM, gestational age, hypertensive disorder, and APH. The adjusted OR for stillbirth in the women with the age over 35 was significantly higher in those women age group 18-24 years (AOR=3.20; 95% CI: 1.36–7.40, $p < 0.041$). The risk of still birth for women in rural residential areas was found to be higher than those living in urban residential areas after adjusting potential factors (AOR=4.69; 95% CI: 3.36–11.20,

$p < 0.022$). The adjusted OR for still birth in women using partograph during pregnancy and the women with the previous history of stillbirth was higher compared with those women with no use partograph during labor or no previous history of stillbirth, respectively (AOR=2.84; 95% CI: 1.45–6.98, $p < 0.030$), (AOR=7.24; 95% CI: 2.41–21.74, $p < 0.001$) (Table 4).

Discussion

In this study, the magnitude of stillbirth was 12.6%, which is in line with studies conducted in Nigeria (12.5%) (11) and Pakistan (12.52 %) (12), whereas it is higher than the results of studies done in Ethiopia, Hosana (8.6%) (13), Tanzania (3.6%) (14), Zambia (3.4%) (15), Malawi (3.6%) (16), and India (10%) (17). The discrepancy might be due to the methodological differences, the care provider competency, the available technology, topography, and the infrastructure of the study. Also, the health seeking behavior of pregnant mothers in the study area might not have been the same.

Mothers over 35 years of age were 4 times higher at risk of stillbirth than those in 15-24 age groups. This finding is in agreement with a study done in Taiwan, Ethiopia, Tanzania and Canadian (18-20). The reasons that stillbirth rates increase with maternal age are currently unclear. A possible explanation for this association could be chronic diseases. With advancing age, the prevalence of chronic diseases such as hypertension and diabetes mellitus increases (21, 22).

The findings of this study showed that women who resided in rural areas were 4.69 times more likely to suffer a still birth than those residing in urban areas. This finding is consistent with studies done in Nepal (23) and Ethiopia (20). This might be due to health care system or health seeking behavior and the life style of the mothers who live in rural areas.

This study also found that participants with no partograph use in labor were in higher odds of facing stillbirth than their counter parts. This finding was consistent with those of studies in Nigeria (24), in Uganda (25), in Nepal (26). Partograph is a chart used to follow up labor recommended by WHO, and the appropriate use of partograph can help health professionals to detect danger signs during labor earlier (27).

In addition, the current study showed that having stillbirth was 2.84-times higher among mothers who had a previous history of stillbirth compared with their counterparts. Similar results have been reported in, Amhara region referral hospitals, Ethiopia (16), and Nigeria (28), Bangladesh (29), Nepal (26), Haryana,

(India) (30). This might be due to the fact that women who had experience of stillbirth in the preceding births were at higher risk of having recurrent stillbirths. Also, poor obstetrics histories are recurrent and the underlying causes are unknown (31).

This study was conducted within a single public hospital on a limited number of participants (small sample size). It does not include private hospitals. Thus, the generalization of results for the entire country is difficult. The study was carried out through cross-sectional method; therefore, it cannot show temporal relationships.

Conclusion

These findings of this study reflected the high prevalence of stillbirth in Hara, Eastern Ethiopia, which is a big health care concern. High maternal age, rural residential areas, the use of partograph during labor, and the previous history of still birth were found to be associated with stillbirth. The identified determinants of stillbirth are manageable and can be amenable to interventions. Therefore, appropriate

prevention strategies during ante partum, intrapartum and newborn care should be applied in order to tackle the risk factors of stillbirth.
